Microscopic Anatomy and Organization of Skeletal Muscle

The microscopic anatomy of skeletal muscle is made up of: endomysium, epimysium, fascicle, fiber, myofilament, myofibril, perimysium, sarcolemma, sarcomere, sarcoplasm and tendon. Endomysium- Thin connective tissue investing each muscle. Epimysium- Connective tissue ensheathing the entire muscle. Fascicle- Discrete bundle of muscle cells.

Microscopic Anatomy of Skeletal Muscle by Bayli Anderson

Myofibrils are cylindrical in shape and run the length of the muscle fiber. The striations of skeletal muscle fibers are formed by the placement of myofilaments within units of myofibrils called sarcomeres. A sarcomere extends between two dark lines called the Z lines. A sarcomere contains two types of protein myofilaments.

Microscopic Anatomy of Skeletal Muscle Flashcards | Quizlet

At the macroscopic level, the skeletal muscles are composed of a variety of layers. The outermost is called the epimysium, and it protects skeletal muscles from damaging friction that could occur as they move against other muscles and bones. The epimysium is a particularly important component in the anatomy of the skeletal muscles because it, along with other connective tissues, forms the muscle tendon.

Skeletal muscles consists of fascicles, but fascicle arrangement vary, producing muscles with different structures and functional properties. Circular. The pattern is circular when the fascicles are arranged in concentric rings; circular muscles are typically found surrounding external body openings which they close by contracting.

Microscopic Anatomy of the Skeletal Muscle

Muscle is the main site for the conversion of chemical energy to mechanical energy, and much of its functions are attributed to the microanatomy of the muscle cell. Each muscle is composed of numerous muscle fibers. Each muscle fiber is composed of multinucleated, cross striated cylindrical muscle cells which are known as myofibrils.
